Setup to Control
a Satellite
Servicing Robot

Augmented Reality

Microsoft HoloLens 1

Project Overview

Create an interface that allows a user to manipulate as well as visualize a robot in real time.

Goals:

- Save time and resources
- Reduce future error through mission planning
- Improving the way operators visualize their environment

Developed in

Key Features

Dragging and Dropping a Robot into the Scene

Communication over ROS

Inverse kinematics

Singular joint movement using slider

Simulating satellite repair missions

Future Work

- Add fine tuning to slider functionality
- Stream data from Qualysis to the Hololens
- Explore its usage for mission planning
- Conduct experiments to compare the effectiveness of the Hololens compared to conventional methods
- Upgrade to the Hololens 2 to expand our capabilities

Challenges Faced and Lessons Learned

- Learning Unity from the ground up (how to use C#)
- Ensuring that the things I made were versatile
- The limited field of view of the Hololens made design difficult
- The limited input options made design difficult
